Teaser for work with Ahmed Abdalla, Stefano Antonini, and Adam Levine.

# The Hilbert space of two-sided black holes: The factorisation puzzle

Consider the Hilbert space of two-sided black holes.

In AdS/CFT,  
according to ER=EPR

$$\mathcal{H}_{\text{bulk}} = \mathcal{H}_L \otimes \mathcal{H}_R$$

$\neq$

Bulk Hilbert space,  
in a  $G_N^{-1}$  expansion

# An example that makes things concrete: 2D gravity coupled to matter

For example, in the simplest model of gravity (JT gravity)  
coupled to matter,

$$\mathcal{H}_{\text{bulk}}^{\text{pert}} = L^2(\mathbb{R}) \otimes \mathcal{H}_{\text{matter}}$$

$\mathcal{H}_{\text{matter}}$  can be decomposed into unitary irreps of  $\widetilde{SL}(2, \mathbb{R})$

Different basis choices,

$$|\ell, \Delta, m\rangle \Leftrightarrow |E_L, E_R, \Delta\rangle \Leftrightarrow |\beta_L, \beta_R, \Delta\rangle$$

The fact that the Hilbert space of two-sided black holes seems different than the factorised boundary Hilbert space is known as the factorisation puzzle.

It was often thought that resolving this puzzle requires a detailed knowledge about the UV.

[Harlow '16, Guica, Jafferis '17, Harlow, Jafferis '18]

The purpose of this talk is to propose a resolution to this puzzle using the low-energy theory.

We will show that non-perturbative corrections to the gravitational path integral lead to

$$\mathcal{H}_{\text{bulk}} = \mathcal{H}_L \otimes \mathcal{H}_R$$

... different than the factorization puzzle.

$$Z(\beta_L)Z(\beta_R) \neq Z(\beta_L, \beta_R)$$

# Another way to describe the lack of factorisation: Algebraic classification of gravitational observables

What is the algebra of observables in the left sub-region?

Factorisation

*Type III*  
 $G_N = 0$

Familiar notions  
cannot be defined:  
 $\text{Tr}, \rho, |\psi\rangle, S$

*Type II*  
 $G_N \rightarrow 0$

Familiar notions  
become better defined  
but still no pure states.  
[for examples, see Witten '21]

*Type I*  
 $G_N$  finite  
According to AdS/CFT  
pure states are well defined  
 $\Leftrightarrow$   
 $\mathcal{H}_{\text{bulk}} = \mathcal{H}_L \otimes \mathcal{H}_R$

# Strategy

Using the gravitational path integral, prove that

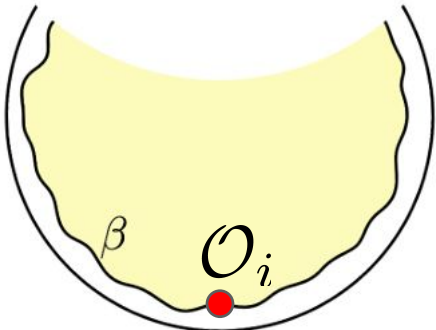

$$\mathrm{Tr}_{\mathcal{H}_{\mathrm{bulk}}}(k_L k_R) = \mathrm{Tr}_{\mathcal{H}_L}(k_L) \mathrm{Tr}_{\mathcal{H}_R}(k_R), \quad \forall k_{L,R} \in \mathcal{A}_{L,R}$$

In this talk, we will only focus on

$$k_L = e^{-\beta_L H_L}, \quad k_R = e^{-\beta_R H_R}.$$

What is  $\mathcal{H}_{\text{bulk}}$ ?

To have a hope of seeing factorisation, we need to break the gauge constraint  $H_L = H_R$ .

$$\mathcal{H}_{\text{bulk}}(K) \equiv \text{Span } \{|q_i\rangle =$$

$$\text{for } E_L, E_R \in \mathcal{E}, i = 1, \dots, K\}$$

Arbitrary energy  
interval

For simplicity,  
 $\Delta_1 \approx \dots \approx \Delta_K = \Delta$

These are “Bag Of Gold” states.

Strategy: calculate the statistics of the trace

$$= \underbrace{(M^{-1})_{ij}}_{\text{Generalized inverse}} \langle q_i | e^{-\beta_L H_L} e^{-\beta_R H_R} | q_j \rangle, \quad M_{ij} \equiv \langle q_i | q_j \rangle.$$

While we might not know these inner-products exactly, we now believe that we can compute their statistics:

$$\overline{|\langle q_i | q_j \rangle|^2} = \text{[Diagram 1]} \text{ [Diagram 2]} = \text{[Diagram 3]} \text{ [Diagram 4]} + \text{[Diagram 5]} + \dots,$$

The diagrammatic expansion shows the squared inner product  $\overline{|\langle q_i | q_j \rangle|^2}$  as a sum of surfaces. The first two terms are unknown (marked with '?') and represent the inner product squared. The third term is a sum of three surfaces: two spheres with red arcs and one genus-2 surface with two red arcs. The vertices are labeled  $i, i^\dagger, j, j^\dagger$ .

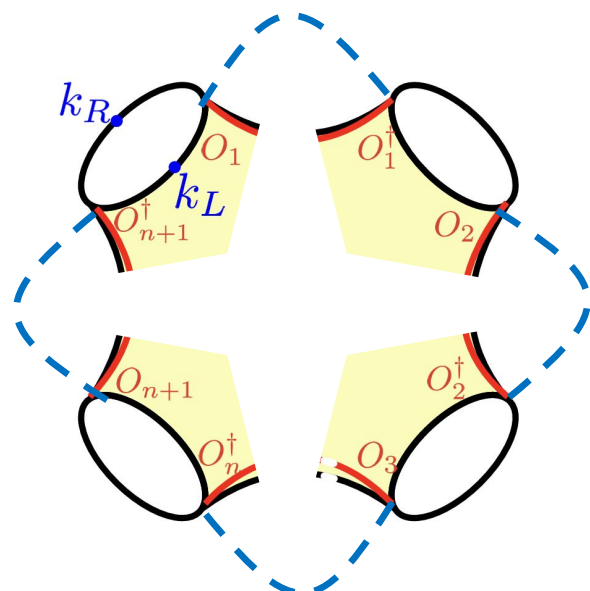

Not necessarily an ensemble, maybe a coarse-graining of a regular UV complete theory.

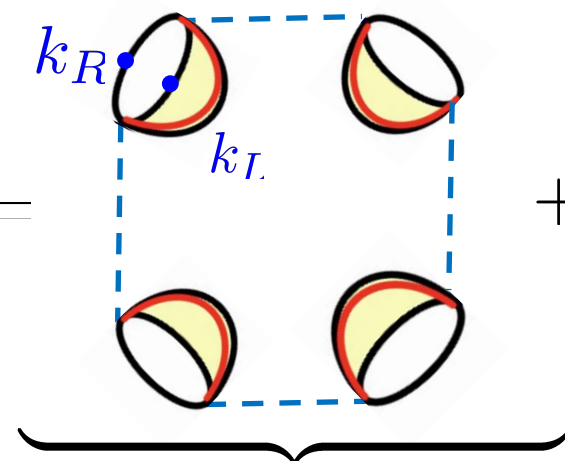

Strategy: calculate the statistics of the trace

Using this assumption, we can compute,

$$\lim_{n \rightarrow -1} \overline{\langle q_i | q_{i_1} \rangle \cdots \langle q_{i_{n-1}} | q_j \rangle \langle q_i | e^{-\beta_L H_L} e^{-\beta_R H_R} | q_j \rangle}$$

$= \lim_{n \rightarrow -1}$

$=$ 

$\underbrace{\hspace{15em}}_{\text{Leading geometry in } e^{S_0}}$

$+ \dots$

No factorisation from the leading geometries in  $e^{S_0}$

If we only included the leading geometries in  $e^{S_0}$ , then we would never see factorization:

$$= \sum_{i=1}^K \frac{\langle q_i | e^{-\beta_L H_L} e^{-\beta_R H_R} | q_i \rangle_{\text{pert}}}{\langle q_i | q_i \rangle_{\text{pert}}} \propto K$$

This verifies that perturbatively we will never see that the Hilbert space factorises.  
This is because when we cannot ignore subleading contributions in  $e^{-S_0}$ .

# Which geometries contribute?

$$\overline{\text{Tr}_{\mathcal{H}_{\text{bulk}}(K)}(k_L k_R)} = \lim_{n \rightarrow -1} \left[ \text{Diagram 1} + \text{Diagram 2} + \dots \right]$$

$K e^{4S_0} \quad \sim \quad K^4 e^{-2S_0}$

Therefore, to probe factorisation we need to resum all wormhole geometries in the limit

[similar computations analysis seen in in  
 Pennington, Shenker, Stanford, Yang `20, **Iliesiu**, Hsin, Yang `21,  
 Balasubramanian, Lawrence, Magan, Sasieta `22, Boruch, **Iliesiu**, Yan `23]

# Strategy: from statistics to exact results

How do we prove factorization through statistics?

**Step 1.** To leading order in  $e^{\#G_N^{-1}}$ ,

$$\mathrm{Tr}_{\mathcal{H}_{\mathrm{bulk}}(K)}(e^{-\beta_L H_L} e^{-\beta_R H_R}) = \begin{cases} \mathrm{Tr}_{\mathcal{H}_L}(e^{-\beta_L H_L}) \mathrm{Tr}_{\mathcal{H}_R}(e^{-\beta_R H_R}), & \forall \beta_L, \beta_R, & \text{when } K \geq d^2, \\ \text{Complicated non-factorising trace,} & & \text{when } K < d^2, \end{cases}$$

We can also go beyond leading order.

Strategy: from statistics to exact results

Define,

$$(\beta_L, \beta_R) = 0 \quad \Leftrightarrow \quad \mathcal{H}_{\text{bulk}} = \mathcal{H}_L \otimes \mathcal{H}_R$$

(If eigenenergies are non-degenerate)

**Step 2.** To all orders in  $e^{\#G_N^{-1}}$ ,  $\overline{(\beta_L, \beta_R)} = 0$ .

**Step 3.** To all orders in  $e^{\#G_N^{-1}}$ ,  $\overline{(\beta_L, \beta_R)^2} = 0$ .

**Today:** We will mostly focus on Step 1.

# Step 1: factorisation to leading order

To resum all geometries,

we define the resolvent for the matrix  $M_{ij} \equiv \langle q_i | q_j \rangle$

$$\mathbf{R}_{ij}(\lambda) = \left( \frac{1}{\lambda - M} \right)_{ij} \qquad \overline{(M^n)_{ij} \langle q_i | e^{-\beta_L H_L} e^{-\beta_R H_R} | q_j \rangle} = \frac{1}{2\pi i} \oint_{C_0} d\lambda \, \lambda^n \, \overline{\mathbf{R}_{ij}(\lambda) \langle q_i | e^{-\beta_L H_L} e^{-\beta_R H_R} | q_j \rangle}$$

# A Schwinger-Dyson equation

The resolvent can be expanded in a geometric series,

The diagrammatic expansion of the resolvent  $\mathbf{R}_{ij}$  is shown as a sum of terms representing different self-energy insertions on a propagator line between indices  $i$  and  $j$ .

The first row shows the expansion starting from a single resolvent insertion:

$$i \text{---} \textcircled{\text{R}} \text{---} j + i \text{---} j + i \text{---} \text{[Self-Energy]} \text{---} j + i \text{---} \text{[Self-Energy]} \text{---} \text{[Self-Energy]} \text{---} j + i \text{---} \text{[Large Self-Energy]} \text{---} j + \dots$$

The second row shows the expansion starting from a bare propagator:

$$i \text{---} j + i \text{---} \text{[Self-Energy]} \text{---} \textcircled{\text{R}} \text{---} j + i \text{---} \text{[Large Self-Energy]} \text{---} \textcircled{\text{R}} \text{---} \textcircled{\text{R}} \text{---} j + \dots$$

The third row shows the expansion of the matrix element  $\overline{\mathbf{R}_{ij} \langle q_i | k_L k_R | q_j \rangle}$  with momentum labels  $k_L$  and  $k_R$  on the internal lines of the self-energy insertions:

$$\overline{\mathbf{R}_{ij} \langle q_i | k_L k_R | q_j \rangle} = i \text{---} \text{[Self-Energy with } k_L, k_R \text{]} \text{---} \textcircled{\text{R}} \text{---} j + i \text{---} \text{[Large Self-Energy with } k_L, k_R \text{]} \text{---} \textcircled{\text{R}} \text{---} \textcircled{\text{R}} \text{---} j + \dots$$

# A Schwinger-Dyson equation

For the resolvent,

$$R(\lambda)$$

For the trace,

# The analytic structure of the Schwinger-Dyson equation

While we cannot solve the Schwinger-Dyson exactly, we can constrain the analytic structure of the resolvent.

$$R(\lambda) \sim \frac{K - d^2}{\lambda} \Theta(K - d^2) + R_0 \quad \text{where} \quad d^2 = e^{2S_0} \int_{E_L, E_R \in \mathcal{E}} \rho(E_L) \rho(E_R) dE_L dE_R$$

...and that no other non-analyticities appear on the negative real axis.  
We have a semi-positive definite inner-product even non-perturbatively.

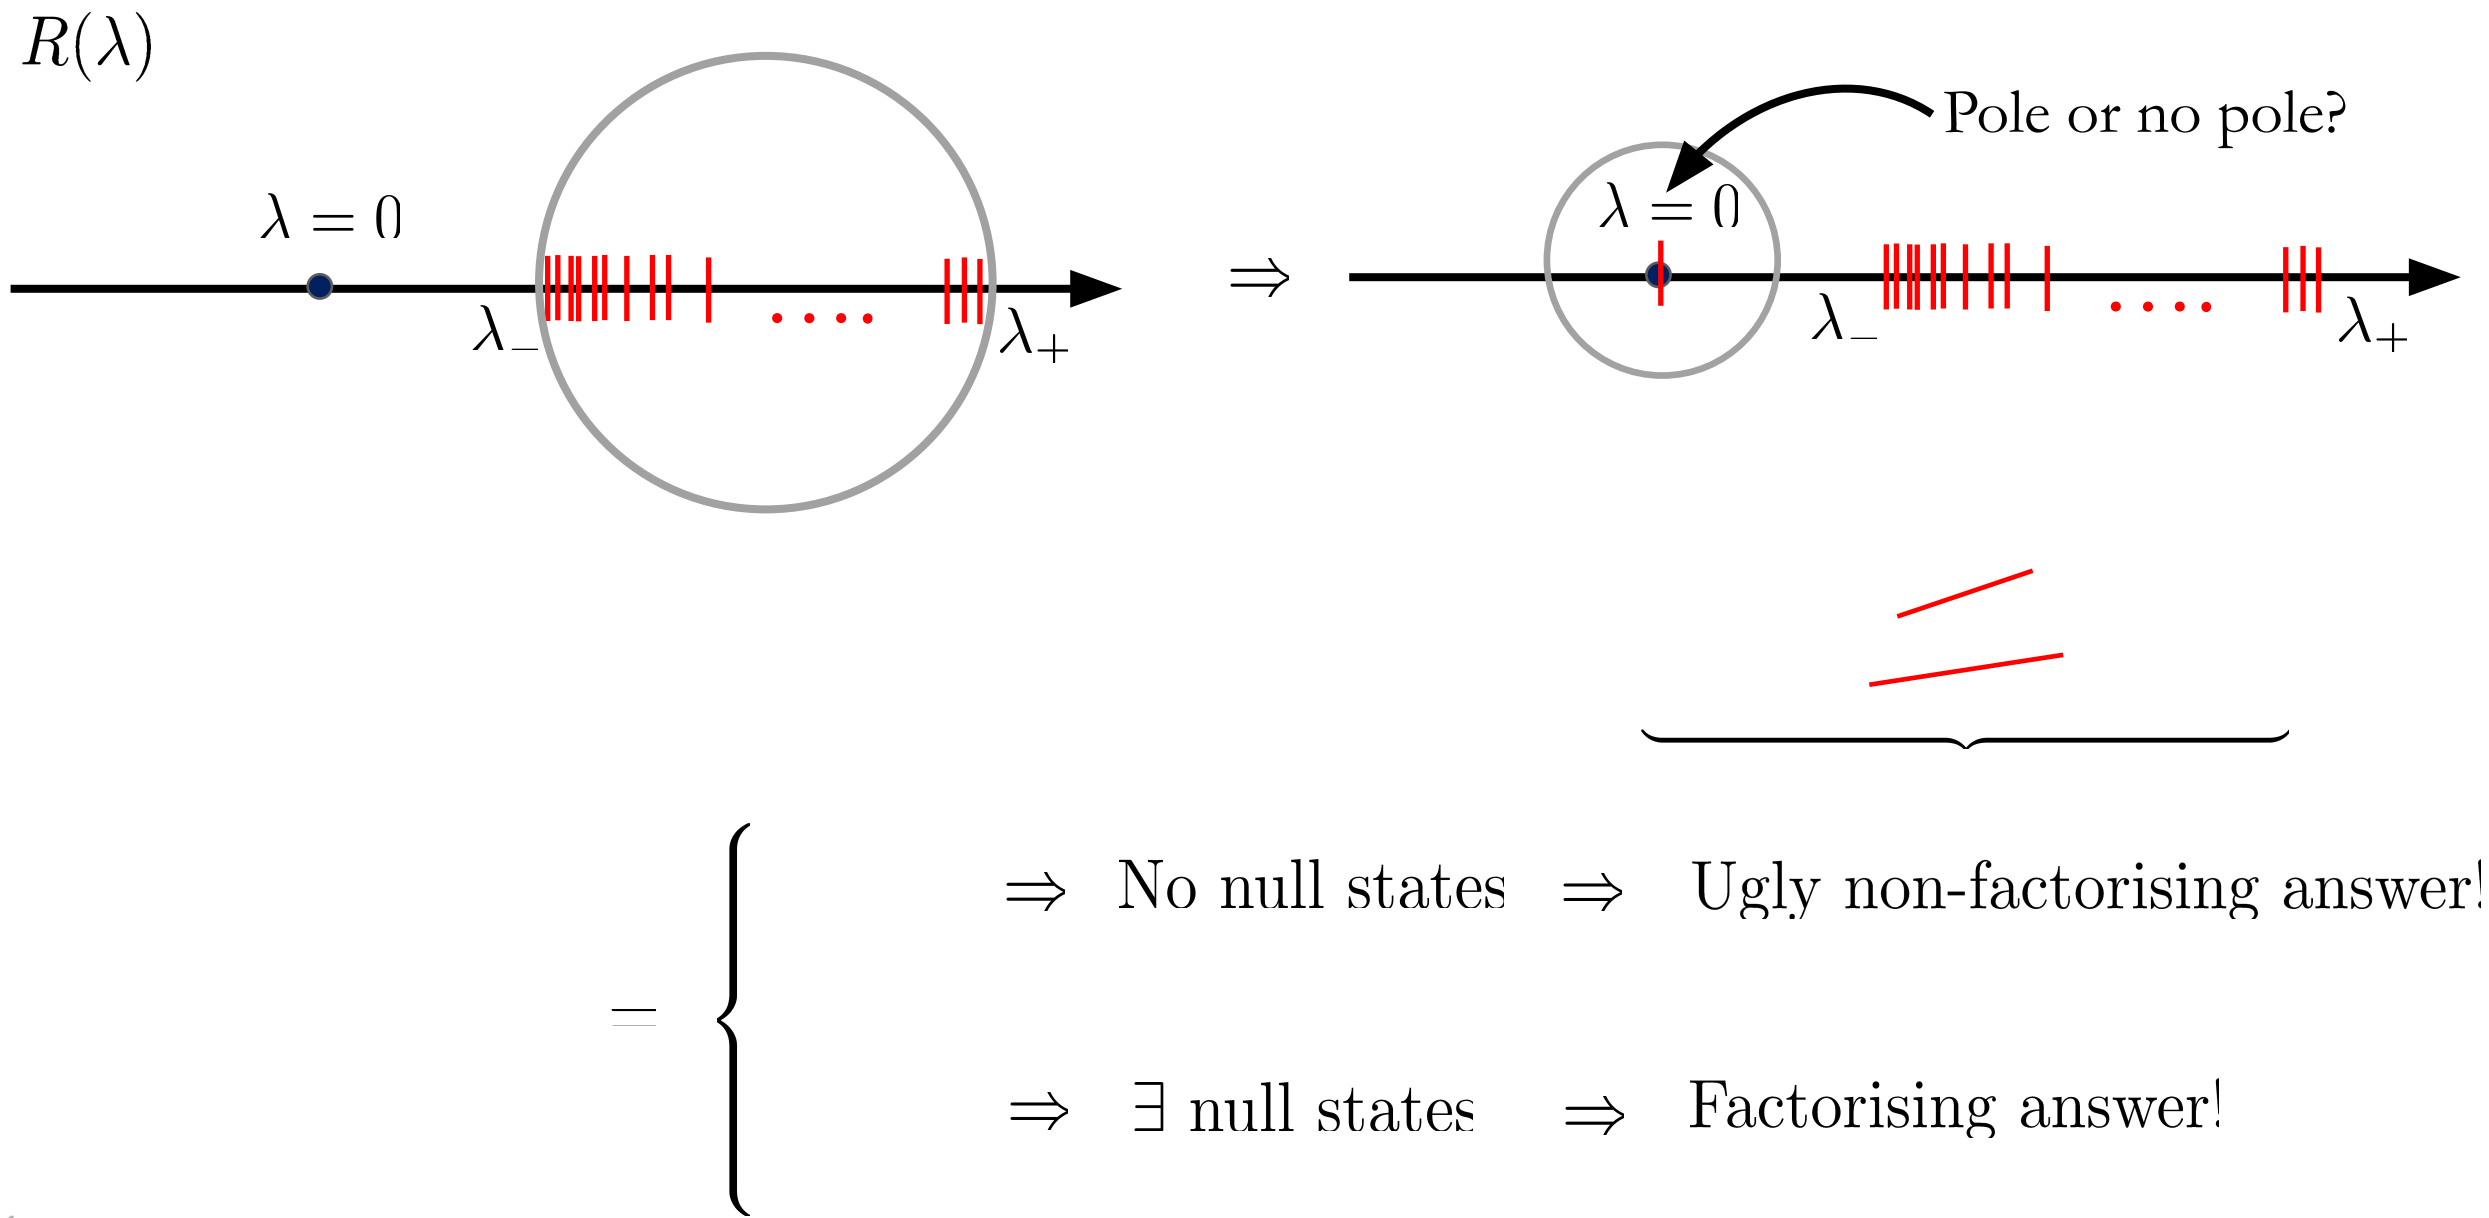

The Hilbert space is finite-dimensional

$$R(\lambda) \sim \frac{K - d^2}{\lambda} \Theta(K - d^2) + R_0$$

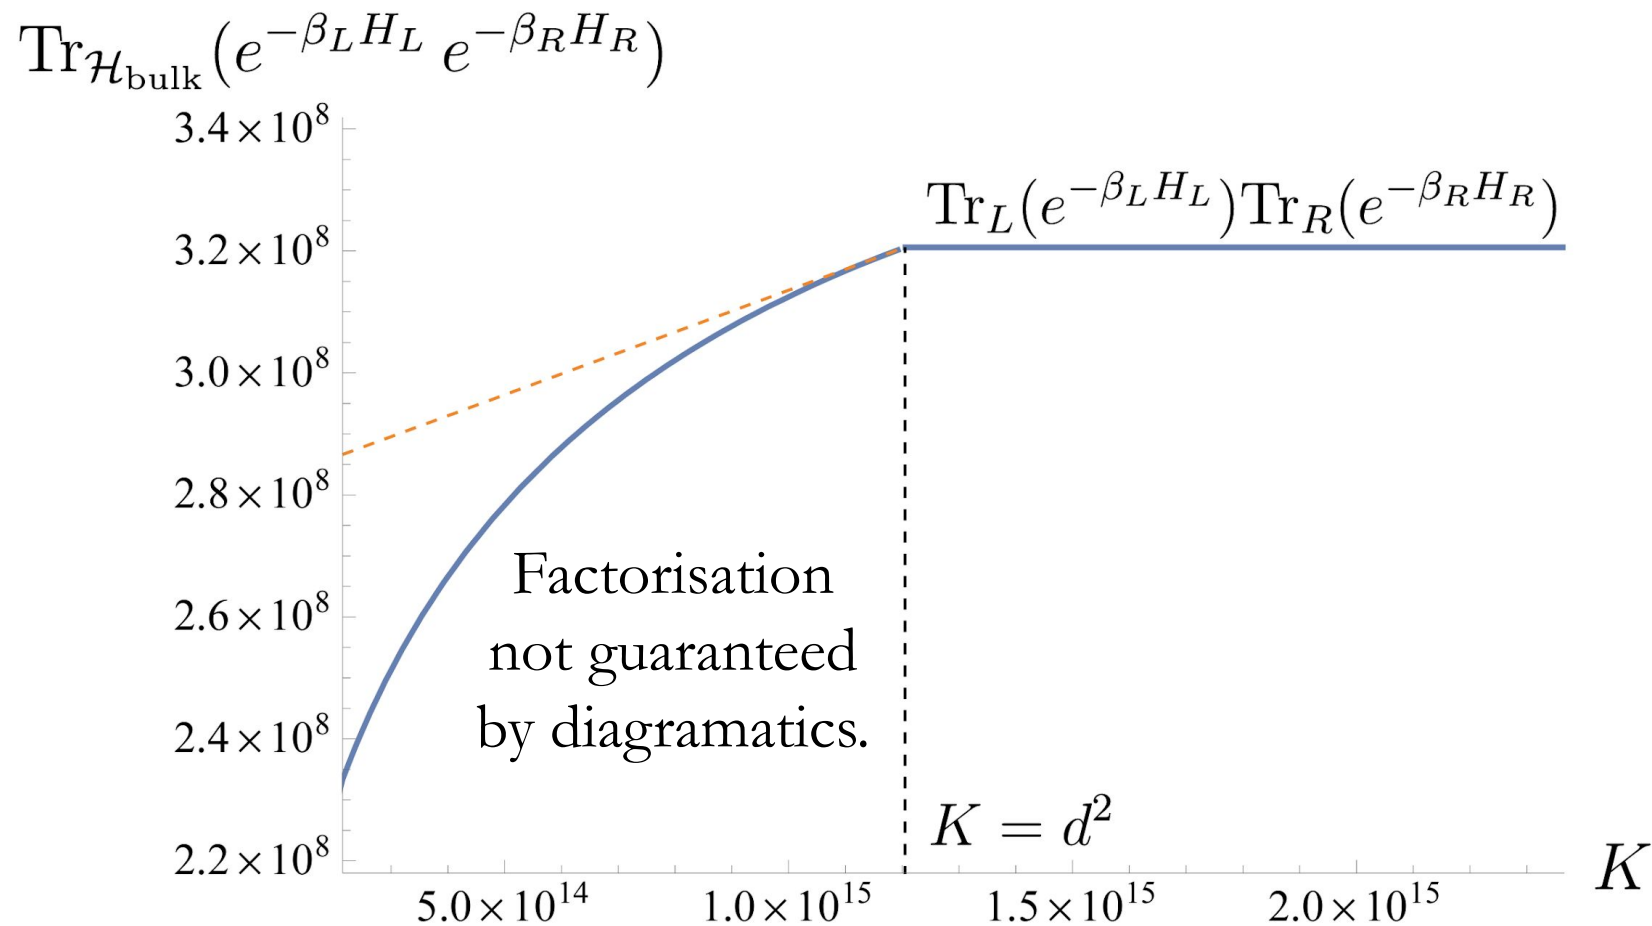

( $\exists$  null states)

# The physical mechanism for factorisation

# The physical mechanism for factorisation

# The “Page curve” of factorisation

Just like the Page curve: a consistency condition for  $\mathcal{H}_{\text{bulk}} = \mathcal{H}_L \otimes \mathcal{H}_R$

# Tracking the differential

We can analyze whether factorisation is exact by studying,

## Proving steps 2 and 3

For large enough  $n$ , we can also show that

$$\begin{aligned} & \overline{\text{Tr}_{\mathcal{H}_{\text{bulk}}(K)}(e^{-\beta_L^{(1)} H_L} e^{-\beta_R^{(1)} H_R}) \dots \text{Tr}_{\mathcal{H}_{\text{bulk}}(K)}(e^{-\beta_L^{(n)} H_L} e^{-\beta_R^{(n)} H_R})} = \\ & = \overline{\text{Tr}_L(e^{-\beta_L^{(1)} H_L}) \text{Tr}_R(e^{-\beta_R^{(1)} H_R}) \dots \text{Tr}_L(e^{-\beta_L^{(n)} H_L}) \text{Tr}_R(e^{-\beta_R^{(n)} H_R})} \end{aligned}$$

to all orders in

# Conclusion

Despite only having access to statistics, we can prove that factorisation occurs exactly before coarse-graining.

$$\overline{(\beta_L, \beta_R)} = 0, \quad \sigma_{\beta}(\beta_L, \beta_R) = 0.$$

# Final comments

1) The one-sided trace is now well defined,

$$\mathrm{Tr}_{\mathcal{H}_{bulk}}(K_L K_R) = (\mathrm{Tr}_{\text{one-sided}} K)^2, \quad K_L = K_R = K \quad \Rightarrow \quad \text{Requirement for Type I algebra}$$

2) Step 1 only involves saddle-points of the Euclidean path integral  $\Rightarrow$  Generalizable to higher dimensions

[Balasubramanian et al. `24, Li `24]

## Final comments

- 3) We assumed there are no degeneracies of the eigenenergies. What if there is a boundary global symmetry (and a bulk gauge symmetry)?

$$\mathrm{Tr}_{\mathcal{H}_{\mathrm{bulk}}}(e^{-\beta_L H_L - \alpha_L^{(i)} Q_L^{(i)}} e^{-\beta_R H_R - \alpha_R^{(i)} Q_R^{(i)}}) = \mathrm{Tr}_{\mathcal{H}_L}(e^{-\beta_L H_L - \alpha_L^{(i)} Q_L^{(i)}}) \mathrm{Tr}_{\mathcal{H}_R}(e^{-\beta_R H_R - \alpha_R^{(i)} Q_R^{(i)}})$$

To define  $\mathcal{H}_{\mathrm{bulk}}$  we need to have particles in all irreps of the gauge group  $\Rightarrow$  **Completeness conjecture**

- 4) There are exceptions to having degeneracies that can be split by bosonic charges:  
e.g. BPS states.

$$\mathrm{Tr}_{\mathcal{H}_{\mathrm{bulk}}}(k_L k_R) = \mathrm{Tr}_{\mathcal{H}_L}(k_L) \mathrm{Tr}_{\mathcal{H}_R}(k_R), \quad k_{L,R} = e^{-\alpha_{L,R} \pi_{\mathrm{BPS}} \overbrace{\mathcal{O}_{L,R}}^{\text{Simple operator}} \pi_{\mathrm{BPS}}}.$$

we can prove that this occurs exactly when  $K > d_{\mathrm{BPS}}^2$ .  $\Rightarrow$  **Factorisation for two-sided BPS BHs**

# Final comments

5) Null states galore!  $|E_L, E_R, \Delta\rangle, |\ell, \Delta, m\rangle \Rightarrow |E_L^{(i)}, E_R^{(j)}\rangle$

[see **Iliesiu**, Levine, Lin, Maxfield, Mezei '24]  $\Downarrow$

No linear operator measures connectedness and the length stops having a geometric meaning.

What does this imply for an infalling observer?  
Do the observables they measure correspond to linear operators on

# Final comments

**Issue:** No good non-perturbative notion of an observer with respect to which we can dress the observables that they measure.

In two-sided black holes,

[see **Iliesiu**, Levine, Lin, Maxfield, Mezei '24 for examples]

Even more problematic, in a closed universe,

[Marolf, Maxfield '20, Usatyuk, Wang, Zhao '24]

# Final comments

[Abdalla, Antonini, **Iliesiu**, Levine '25]

[see also Harlow, Usatyuk, Zhao '25]

The inner-products in the Hilbert space

that describes the physics seen by an observer,

*Closed universe example*

The same resolvent computation from before now yields,

Concrete framework to quantify the non-perturbative quantum gravity effects seen by a gravitating observer.

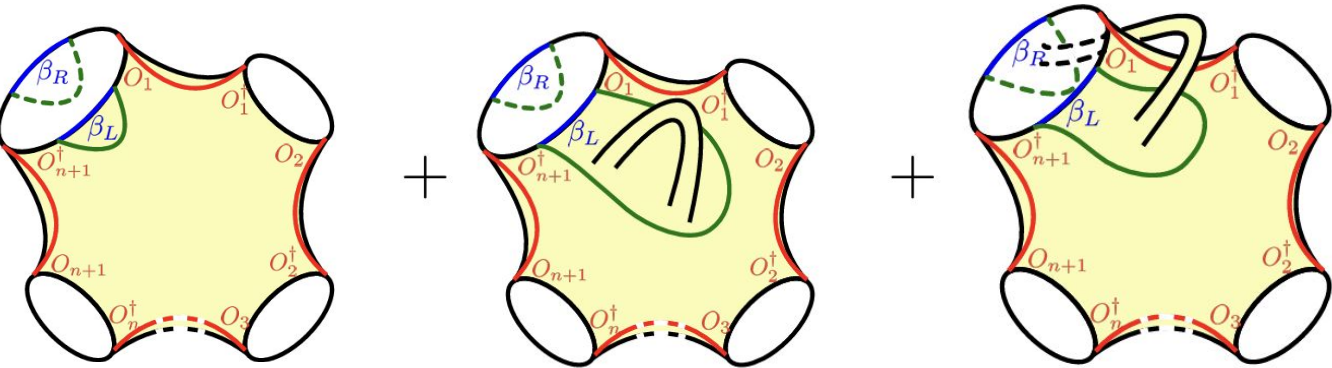

**Thank you!**

## **Additional details**

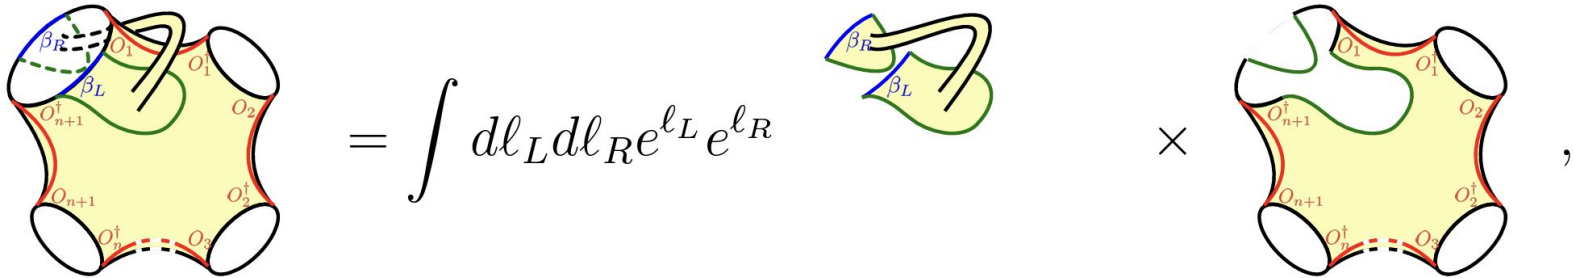

Going to even higher orders in

We can include higher genus corrections,

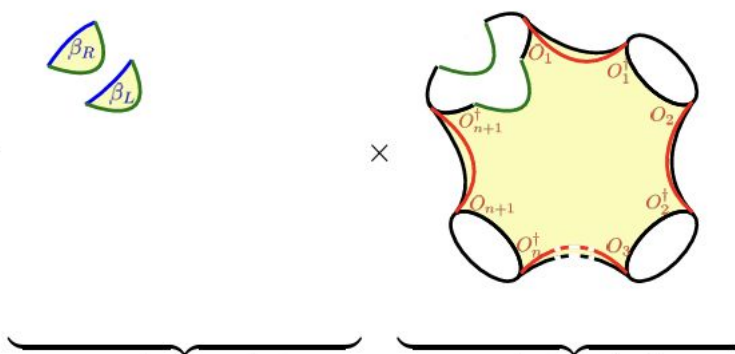

$$\overline{\mathbf{R}_{ij} \langle q_i | k_L k_R | q_j \rangle} =$$

but suppress non-planar index contractions by taking  $K \rightarrow \infty$  first.

We can perform a decomposition into geometries we've encountered before:

The same pinwheel geometry was encountered at finite K:

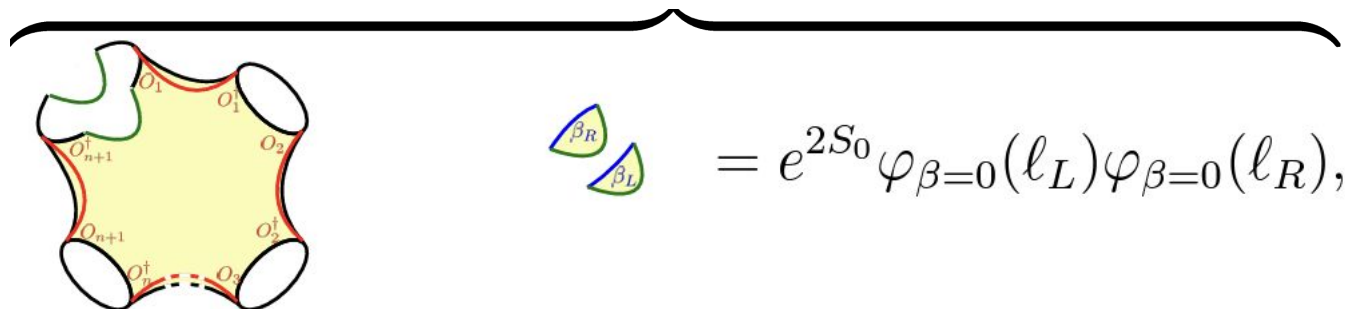

$$Tr(k_L k_R) = \langle \beta_L | \hat{O} | \beta_R \rangle = \int d\ell_L d\ell_R e^{\ell_L} e^{\ell_R}$$

The diagram consists of two parts. On the left, there are two green sectors, one labeled  $\beta_R$  and one labeled  $\beta_L$ . On the right, there is a yellow pinwheel geometry with vertices labeled  $O_1, O_1^\dagger, O_2, O_2^\dagger, \dots, O_{n+1}, O_{n+1}^\dagger$ . The sectors and the pinwheel are connected by a multiplication symbol  $\times$ . Below the sectors and the pinwheel, there are two horizontal curly braces, one under the sectors and one under the pinwheel.

Projector onto infinite temperature state

Using the results,

when  $K > d^2$ .

The diagram shows a yellow pinwheel geometry with vertices labeled  $O_1, O_1^\dagger, O_2, O_2^\dagger, \dots, O_{n+1}, O_{n+1}^\dagger$ . To the right of the pinwheel, there are two green sectors, one labeled  $\beta_R$  and one labeled  $\beta_L$ . To the right of the sectors, there is an equation:  $= e^{2S_0} \varphi_{\beta=0}(\ell_L) \varphi_{\beta=0}(\ell_R)$ . A large horizontal curly brace is positioned above the pinwheel and the sectors.

# Step 1: Going to even higher orders

The diagrammatic equation illustrates the factorization of a higher-order genus surface. On the left, a genus- $n$  surface (yellow) with boundary operators  $O_1, O_2, \dots, O_{n+1}$  and  $O_1^\dagger, O_2^\dagger, \dots, O_{n+1}^\dagger$  is shown. This is equated to an integral over lengths  $l_L, l_R$  of a genus-1 surface (green) with boundary operators  $O_1, O_1^\dagger$  and  $O_2, O_2^\dagger$ , multiplied by a genus-0 surface (yellow) with boundary operators  $O_1, O_1^\dagger$  and  $O_2, O_2^\dagger$ .

$$= \int d\ell_L d\ell_R e^{\ell_L} e^{\ell_R} \times$$

$$\overline{\text{Tr}_{\mathcal{H}_{bulk}(K>d^2)}(e^{-\beta_L H_L} e^{-\beta_R H_R})} = \underbrace{\overline{\text{Tr}_{\mathcal{H}_L}(e^{-\beta_L H_L}) \text{Tr}_{\mathcal{H}_R}(e^{-\beta_R H_R})}}_{\int_{\mathcal{E}} dE_L dE_R \overline{\rho(E_L) \rho(E_R)} e^{-\beta_L E_L - \beta_R E_R}} + O\left(\frac{1}{K}\right).$$

Consistent with factorisation before coarse-graining. However, we want to probe factorisation more directly.

## Step 2 & 3: Going to even higher orders

We can similarly show that,

$$\begin{aligned} & \overline{\text{Tr}_{\mathcal{H}_{\text{bulk}}(K)}(e^{-\beta_L^{(1)} H_L} e^{-\beta_R^{(1)} H_R}) \dots \text{Tr}_{\mathcal{H}_{\text{bulk}}(K)}(e^{-\beta_L^{(n)} H_L} e^{-\beta_R^{(n)} H_R})} = \\ & = \overline{\text{Tr}_L(e^{-\beta_L^{(1)} H_L}) \text{Tr}_R(e^{-\beta_R^{(1)} H_R}) \dots \text{Tr}_L(e^{-\beta_L^{(n)} H_L}) \text{Tr}_R(e^{-\beta_R^{(n)} H_R})} \end{aligned}$$

Considering two 2-sided traces:

$$\overline{d(\beta_L, \beta_R)} \equiv \mathcal{D}_{\beta_L, \beta_R, \beta'_L, \beta'_R} \overline{Z_{\text{bulk}}(\beta_L, \beta_R) Z_{\text{bulk}}(\beta'_L, \beta'_R)}|_{\beta'_{L/R} = \beta_{L/R}} \quad \mathcal{D}_{\beta_L, \beta_R, \beta'_L, \beta'_R} \equiv \partial_{\beta_L} \partial_{\beta_R} - \partial_{\beta'_L} \partial_{\beta'_R}$$

$\Downarrow$

$$\overline{d(\beta_L, \beta_R)} = 0$$

Considering four 2-sided traces:

$$\overline{d(\beta_L, \beta_R)^2} = 0$$

Details about the dimension of

The same resolvent computation from before now yields,
