UV - IR group homomorphism

- In condensed matter physics, we are usually interested in understanding the possible phases of matter when the UV description has a global symmetry group $G = G_{UV}$
- In general there is an IR fixed point that governs the universal behavior (TQFT, CFT, etc).

The IR fixed point has a symmetry group G_{IR} containing internal and space-time symmetries

- There is a UV-IR group homomorphism $\rho : G_{UV} \rightarrow G_{IR}$

ρ can be viewed as a **topological invariant** of the UV system

This means we have a **collection** of RG flows from the UV to IR, one for each symmetry defect configuration

- We can have **different** UV theories described by **same** IR fixed point, but different $\rho \rightarrow$ **symmetry-enriched phase of matter**

IR symmetries and higher categories

- In general, the IR symmetry is **not a group**
- For a $(d+1)$ D TQFT, it is expected to be a **fusion d-category** $\mathcal{B}^{(d+1)}$

This is understood using the correspondence

Symmetry \longleftrightarrow Topological defects

The higher category is characterizing topological defects of varying codimension and their mutual interactions

Fusion d-category of topological defects in (d+1)D TQFTs

0-morphisms:
Codimension-1 defects
gapped domain walls

1-morphisms:
Codimension-2 defects
Domain walls between
domain walls

2-morphisms:
Codimension-3 defects
Domain walls between
codimension-2 defects

- Continue until we get to d-morphisms (codimension-(d+1) defects \rightarrow maps between codimension-d defects)

Fusion d-category of topological defects in (d+1)D TQFTs

Tensor structure: Can fuse defects

0-morphisms: Codimension-1 defects;
gapped domain walls

1-morphisms: Codimension-2 defects;

2-morphisms: maps between codimension-2 defects

Example: Symmetry of (2+1)D topological phases of matter

IR categorical symmetry

- Unitary modular tensor category of anyons \mathcal{C}

$$\begin{array}{c} a \\ \swarrow \\ \alpha \\ \searrow \\ e \end{array} \begin{array}{c} b \\ \swarrow \\ \beta \\ \searrow \\ d \end{array} \begin{array}{c} c \\ \swarrow \\ \mu \\ \searrow \\ f \end{array} = \sum_{f, \mu, \nu} [F_d^{abc}]_{(e, \alpha, \beta)(f, \mu, \nu)} \begin{array}{c} a \\ \swarrow \\ \nu \\ \searrow \\ d \end{array} \begin{array}{c} b \\ \swarrow \\ f \\ \searrow \\ \mu \end{array} \begin{array}{c} c \\ \swarrow \\ \mu \\ \searrow \\ \nu \end{array}$$

$$\begin{array}{c} a \\ \swarrow \\ \mu \\ \searrow \\ c \end{array} \begin{array}{c} b \\ \swarrow \\ \mu \\ \searrow \\ c \end{array} = \sum_{\nu} [R_c^{ab}]_{\mu\nu} \begin{array}{c} a \\ \swarrow \\ \nu \\ \searrow \\ c \end{array} \begin{array}{c} b \\ \swarrow \\ \nu \\ \searrow \\ c \end{array}$$

- 0-form invertible symmetry: braided tensor autoequivalences $\text{Aut}(\mathcal{C})$

$$\begin{array}{c} a \\ \swarrow \\ \varphi \\ \searrow \\ \mu \end{array} \begin{array}{c} b \\ \swarrow \\ \varphi \\ \searrow \\ \mu \end{array} = \sum_{\nu} [U_{\varphi}(a, b; c)]_{\mu\nu} \begin{array}{c} a \\ \swarrow \\ \nu \\ \searrow \\ \varphi \end{array} \begin{array}{c} b \\ \swarrow \\ \nu \\ \searrow \\ \varphi \end{array}$$

- Symmetry fractionalization data:

$$\begin{array}{c} \varphi \\ \swarrow \\ x \\ \searrow \\ \varphi \circ \vartheta \end{array} \begin{array}{c} \vartheta \\ \swarrow \\ \varphi \circ \vartheta \\ \searrow \\ \varphi \end{array} = \eta_x(\varphi, \vartheta) \begin{array}{c} \varphi \\ \swarrow \\ x \\ \searrow \\ \varphi \circ \vartheta \end{array} \begin{array}{c} \vartheta \\ \swarrow \\ \varphi \circ \vartheta \\ \searrow \\ \varphi \end{array}$$

- And more (F and R symbols of endpoints of codimension-1 defects, non-invertible domain walls, ...)

Symmetry-enriched phases of matter

- Symmetry-enriched phases of matter are properly described by viewing the UV symmetry group G_{UV} as a higher category \mathcal{G}_{UV}^{d+1}

0-morphisms

1-morphisms:
junctions between
0-morphisms

2-morphisms:
maps between
1-morphisms

Symmetry-enriched phases of matter and higher homomorphisms

- And now we have a higher $(d+1)$ -homomorphism

$$\rho^{d+1} : \mathcal{G}_{UV}^{d+1} \rightarrow \text{Inv}(\mathcal{B}^{d+1})$$

- Specializing to $(2+1)$ D symmetry-enriched gapped phases of matter gives the framework of G -crossed braided tensor categories

MB, Bonderson, Cheng, Wang arXiv:1410.4540

See also: Etingof, Nikshych, Ostrik 2010; Jones, Penneys, Reuter 2023

- All topological phases of matter can be understood this way
(SPTs, topological insulators, FQH states, quantum spin liquids, anomalies, etc)

$\mathcal{B}^{d+1}, \rho^{d+1}$ characterize symmetry-enriched topological phases

Outlook

- It is crucial to unpack these abstract mathematical structures (**abstract nonsense**) into concrete algebraic data, consistency equations, and equivalence relations (**skeletonization**)

e.g. MB, Bonderson, Cheng, Wang 2014

This is a job for physicists

- It is important to relate these mathematical structures to the **operator algebra** that describes the UV lattice model or quantum field theory
- What is the full symmetry structure of a gapless QFT in $(d+1)D$? \mathcal{B}^{d+2} ?
- We should develop efficient **computational algorithms** that can:
 - Give the complete classification / characterization of phases of matter given the symmetries of interest
 - Determine the full set of topological data characterizing a phase of matter given only access to ground state correlators.

Relevant for quantum state tomography in quantum computing
